

Intelligence — Install on Mac

Intelligence — Install on Mac (No Docker)

These instructions are for Mac only. When you're done, the app runs at **http://localhost:8001**, the news scheduler runs automatically, and you control everything with two commands.

What you need before starting

You need four tools. The install script will offer to install any that are missing — but it's helpful to know what they are first.

Tool	What it does
Homebrew	A Mac package manager — it installs software the easy way
Python 3.11+	Runs the Intelligence server and AI engine
Node.js 18+	Builds the web interface
Git	Downloads the code and keeps it up to date

You also need a free Gemini API key — the install script will ask for it and tell you where to get one (30 seconds, no credit card).

Step 1 — Install Homebrew (if you don't have it)

Homebrew is a free tool that lets you install software on a Mac from the Terminal with a single command. Think of it as an App Store for developer tools.

Check if you already have it: open Terminal (press **⌘** Space, type **Terminal**, press Enter) and run:

```
brew --version
```

If you see a version number, you already have Homebrew — skip to Step 2.

If you see “command not found”, install it by pasting this into Terminal and pressing Enter:

```
/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"
```

This will: - Ask for your Mac password (normal — it needs permission to install software) - Download and install Homebrew (a few minutes) - Print “Installation successful!” when done

After it finishes, close Terminal and open it again so the new commands are available.

Step 2 — Get the code

You probably have a folder called **intelligence-main** or **intelligence-main-2** from when you downloaded the ZIP from GitHub. That folder is a snapshot — it cannot receive updates with `git pull`. You can leave it where it is; it won't interfere with anything.

You need a fresh copy from git. Open Terminal and run:

```
cd ~  
git clone https://github.com/jeffcu/intelligence.git  
cd intelligence
```

This creates a folder called `intelligence` in your home folder. All commands from here on run from inside that folder.

If Terminal says “git: command not found”, run `brew install git` first, then retry.

Step 3 — Run the installer

```
bash install.sh
```

The installer will automatically check for Python, Node.js, and Git. If any are missing, it will ask if you want to install them — just press **Enter** or type **y** to say yes.

What the installer does: 1. Checks Python, Node.js, and Git — offers to install anything missing via Homebrew 2. Creates a Python virtual environment inside the project folder (`venv/`) 3. Installs all Python packages (2–4 minutes — one package called `chromadb` is large) 4. Asks you for your Gemini API key and saves it 5. Installs npm packages and builds the web interface

Getting your Gemini API key: when the installer asks, go to <https://aistudio.google.com/apikey>, click “Create API Key”, copy it, and paste it into Terminal. You only do this once.

You only run `install.sh` once. After that, use `start.sh` and `stop.sh`.

Step 4 — Start Intelligence

```
bash start.sh
```

When you see `http://localhost:8001` printed, open that address in your browser. The full interface will be there.

The news scheduler starts automatically in the background. On first start it immediately runs a news fetch — this takes a few minutes while it initialises. After that, the scheduler runs on its own at **7am, noon, and 3pm** every day.

Step 5 — Stop Intelligence

```
bash stop.sh
```

This stops the server and the scheduler cleanly.

Daily use

Every time you want to run Intelligence:

```
cd ~/intelligence
bash start.sh
```

To stop it:

```
bash stop.sh
```

Getting updates

When a new version is released:

```
cd ~/intelligence
bash stop.sh
git pull
bash install.sh
bash start.sh
```

`git pull` downloads the latest code. `install.sh` picks up any new packages and rebuilds the interface.

Troubleshooting

“zsh: command not found: brew” Homebrew isn’t installed or your Terminal needs to be restarted. See Step 1.

API didn’t start / browser shows nothing

```
tail -30 api.log
```

Scheduler not fetching news

```
tail -30 scheduler.log
```

Start over cleanly

```
bash stop.sh
rm -rf venv dist node_modules
bash install.sh
bash start.sh
```

This wipes and rebuilds everything. Your API key in `.env` and your data in `intelligence.db` are kept.

Check if it’s running

```
curl http://localhost:8001/health
```

Should return something like `{"status":"ok","api_key":"configured","db":"exists"}`.
